

BUG: Flanged three-way valve, PN 25/16

How energy efficiency is improved

Accurate control with high reliability.

Areas of application

Continuous control of cold/warm/hot water, water vapour and air in HVAC systems, in closed networks. Water quality as per VDI 2035. Assembly with AVP 242 to AVP 244 actuators as a regulating unit.

Features

- Nominal pressure 25 bar for DN15 to DN150, nominal pressure 16 bar for DN15 to DN80
- Satisfies standard for actuators as per DIN 32730²⁾ 3)
- Control valve contains no silicone grease; painted black
- Nominal diameters DN15 to DN150
- Equal-percentage characteristic
- Linear mixing passage characteristic
- With the spindle retracted, the valve is closed
- Application as control valve or diverting valve
- Temperature range up to 240 °C

Technical description

- Valve with flange connection as per EN 1092-2, Form B, raised face, for PN25 and PN16, depending on type
- Ductile cast iron valve body
- Stainless steel valve seat
- Stainless steel spindle
- Stainless steel plug in nominal diameters DN15 to DN50, with glass-fibre-reinforced Teflon sealing ring
- Stainless steel plug in nominal diameters DN65 to DN150, metal-on-metal seal
- Maintenance-free brass stuffing box with spring-loaded Teflon washer

1) The VUG 065 F316 valves do not have TÜV approval. They do not bear the test institute's code and are classified under Category I of the Directive on Pressure Equipment.

2) At temperatures below 0 °C, use the stuffing box heater; at temperatures above 100 °C, use the temperature adaptor (accessory).

3) DIN 32730 has been substituted by DIN EN 14597.

Valve: Variant F, for technical data and accessories see Valve Type Table
 Drive: Variant F, for technical data, accessories and installation position, see section 71
 Example: VUD 065 F300 / AVP 243 F031
 Valve control passage A-AB is closed when actuator is pressureless = factory setting
 Valve control passage A-AB is open when actuator is pressureless = on request

Δp_{max} [bar]= Maximum permitted pressure difference across the valve at which the drive can still reliably open and close the valve, taking account of Δp_v .
 Δp_s [bar]= Maximum permitted pressure difference across the valve in case of a fault (pipe break downstream of the valve) at which the drive can close the valve reliably with 'fast' performance of the stroke.

Pressure-stroke characteristic (with valve fitted)**Characteristic is not adjustable:**

B10728

Characteristic is adjustable:

B10684

- = CLOSED without pressure (function E)
 = OPEN without pressure (function A)

Sequences with XSP31 are possible**Function**

The valve can be controlled into any desired intermediate position by means of an electric drive. If the valve stem is extended, the control passage of the valve is closed. These valves may be used as control valves. The direction of flow marked on the valve must be observed. Closure with the pressure is not permissible with pneumatic drives, since it would cause pressure surges. Parameters related to flow mechanics conform to EN 60534.

Used as a control valve

B01134a

Description

The key features of these control valves are their high reliability and precision, and they make a major contribution towards environment-friendly control. They meet demanding requirements including safety functions, coping with high differential pressures, controlling the medium temperature and providing a shut-off function; all this is achieved with a low noise level.

An automatic and fixed connection is made between the valve stem and the drive shaft. The Sauter profile plug made of stainless steel controls an equal-percentage flow in the control passage. To compensate the complementary characteristic of the consumer and to guarantee an identical quantity of medium regardless of the valve position, the mixing passage acts with a linear characteristic. The tightness of this valve is guaranteed by the stainless steel ring pressed into the seat and the corresponding valve plug.

The stuffing box is maintenance-free; it consists of 6 conical Teflon rings and a spring. The spring ensures constant tension in the seals, thereby guaranteeing tightness in relation to the valve stem. In addition, a grease reserve ensures constant lubrication of the valve stem. The grease reserve also prevents any particles that might be present in the medium from reaching as far as the Teflon seal.

Engineering and fitting notes

The drive is placed directly on top of the valve and is fixed with screws. The connection between the drive and the valve stem is made automatically. The closing point must be set as described in the installation instructions (MV 506012 AVP 242 or MV 506013 AVP 243/244).

Installation position

The final control element can be installed in any position, except facing downwards. Condensate and water drips etc. must be prevented from penetrating into the drive. With a horizontal installed position, the permitted maximum weight on the valve is 25 kg unless a support is provided by the customer or others.

up to 130 °C: in any position, but not facing downwards.

above 130 °C: at temperatures above 130 °C or 180 °C respectively, the horizontal installed position is recommended and the adaptor corresponding to the temperature must be inserted. However, the adaptor can also serve as an extension so as to bring the drive out of the pipe insulation. The pipes must be insulated to protect the actuator against great heat.

When fitting the drive onto the valve, you must make sure that the plug is not rotated on the stainless steel seat (this would damage the sealing surfaces). If the valve is insulated, the insulation must only extend as far as the connecting clip of the drive.

If there is a requirement for a split range of adjustment, improved setting accuracy, increased setting speed and air rate or reversible direction of operation, the drive can be fitted with positioner XSP 31, see section 79.

Applications with steam

The valves can be used for steam applications up to 200 °C with the same $\Delta p_{\max}$ values shown in the combination tables. However, we advise you only to use the valves for OPEN-CLOSED switching. For use as a control valve, you should make sure that the majority of the work is not done in the lower third of the valve stroke range. In this position, an extremely high flow speed would develop, severely reducing valve's lifetime.

Applications with water

To ensure that impurities in the water (such as welding beads or particles of rust, etc.) are retained and the plug seal is not damaged, it is advisable to install collective filters, e.g. for each storey or pipe run. Water quality requirements conform to VDI 2035. If an additional medium is used, the compatibility of the valve materials must be clarified with the manufacturer of the medium. The Material Table shown below can be used for this purpose. If glycol is used, we recommend that a concentration of between 20% and 55% should be selected.

The valves are not suitable for drinking water or in zones where there is a risk of explosions.

Other notes concerning hydraulics and noises in systems

The valves can be used in a low-noise environment. To avoid noises, the pressure differences Δp listed below should not be exceeded. These are shown as recommended values in the pressure loss table.

Pressure difference Δp_v is the maximum pressure that may be present on the valve, regardless of the stroke position, so that the danger of cavitation and erosion is limited. These values are independent of the drive force. Cavitation accelerates wear and causes noises. To prevent cavitation, which mainly occurs with applications involving vapour or steam, differential pressure $\Delta p_{\max}$ should not exceed value Δp_{krit} :

$$\Delta p_{\text{krit}} = (p_1 - p_v) \times 0,5$$

p_1 = upstream pressure in front of the valve (bar)

p_v = steam/vapour pressure

Absolute pressure is used for the calculations.

The close/off pressure values which are also listed represent the maximum pressures at which the drive can still use its own force to move the valve. It should be pointed out here that if these pressures are used and the pressure difference $\Delta p_{\max}$ is exceeded, the valve may sustain damage due to cavitation and erosion. In case of a spring return function, the stated Δp_s values also represent the permitted differential pressure up to which the drive guarantees closure of the valve in case of an incident. As this is a safety function with 'fast' passage through the stroke (by means of the spring), this value may exceed $\Delta p_{\max}$. The valves are not suitable for drinking water or in zones where there is a risk of explosions.

Plug	1.4305	X 8 Cr Ni S 18-9
Plug seal	PTFE	glass-fibre reinforced
Stuffing box	CW 617 N	Cu Zn 40 Pb 2
Seal under stuffing box	CW024A	Cu-DHP

Detailed information on pressure difference definitions

Δp_v :

Maximum permitted pressure difference across the valve for every position of the stroke, limited by noise level and erosion.

This parameter specifically characterises the hydraulic behaviour of the valve as an element through which a flow passes. Monitoring of cavitation and erosion, and the associated development of noise, will improve the valve's lifetime as well as its usability.

Δp_{max} :

Maximum permitted pressure difference across the valve at which the drive can reliably open and close the valve.

The following are taken into account: static pressure and influences related to flow mechanics. Faultless performance of the stroke and tightness are guaranteed with this value, and in no case is valve value Δp_v exceeded.

The following are included: static pressure and fluidic influences. This value ensures that the stroke movement and the valve closure are performed properly. Furthermore, the Δp_v value of the valve is never exceeded.

Δp_s :

Maximum permitted pressure difference across the valve in case of a fault (such as a voltage failure, excessive increase in temperature and pressure, and pipe break) at which the drive can close the valve tightly and can hold the full operating pressure against atmospheric pressure if need be. As this is a safety function with a 'fast' performance of the stroke, Δp_s may be greater than Δp_{max} or Δp_v . The disruptive influences arising here in connection with flow mechanics are quickly passed through, and are of secondary importance in this functioning mode.

For three-way valves, the values only apply to the control passage.

Δp_{stat} :

Line pressure across the valve. Essentially corresponds to the dead pressure with the pump switched off, caused (for example) by the fluid level in the system, increase in pressure due to the pressure tank, steam pressure, etc.
